

The Logarithmic Time Scale

Enigma Factsheet · The Logarithmic Time Scale

In 1979, Tad Mann introduced the principle of The Logarithmic Time Scale. The two starting points are that life begins at conception and that, as we grow older, time seems to pass more slowly.

Logarithmic

The time scale runs logarithmically, meaning that the speed continuously decreases. Initially the speed is more than a full sign per month; at the age of 70 it is less than one degree per year.

The speed continues to decrease. When a person reaches 77 years of age, they arrive at the point where the time scale began.

From Conception

The count begins from conception. That moment corresponds to a position of 120 degrees before the ascendant. If you use equal houses from the ascendant, this is cusp 9. Tad Mann, incidentally, prefers the Placidus system.

At birth, the point on the Logarithmic Time Scale is at the ascendant.

Interpretation

Tad Mann views the point on the Logarithmic Time Scale as an important indicator of experiences in life. The point itself has no substantive meaning; it is merely a marker of time.
