

Invisible Luminaries Astrology

Invisible Luminaries Astrology (ILA) has its origins with the French astrologer Dom Neroman. The approach was further developed by another French astrologer: Jean Carteret. It was the Dutch astrologer George Bode who gave ILA its definitive form. At present, the technique is used primarily in the Netherlands.

The main characteristics of ILA

- The use of the empty foci in the Keplerian ellipses formed by the celestial bodies: the Black Moon and the Black Sun. Astronomically, these are the aphelion for the Sun and the apogee for the Moon.
- The introduction of two hypothetical planets beyond the orbit of Pluto: Persephone and Vulcanus.
- The introduction of points that form oppositions or squares with the lunar nodes or with the aphelion and the apogee.
- A redefinition of the rulerships.

Black Moon

The Black Moon is the empty focus in the orbit of the Moon. It coincides with the apogee, the point in the lunar orbit that lies at the greatest distance from the Earth.

Because the orbit of the Moon is very irregular, corrections have been introduced to calculate the Corrected Black Moon. The most popular approach is that of Max Duval, who unfortunately did not explain his method and did not provide a formula. We only have his printed ephemeris at our disposal. The Dutch astrologer Cees Jansen succeeded in devising a formula that approximates Duval's values very closely, usually within one arc minute, but always within 3 arc minutes.

The Swiss Ephemeris offers an alternative approach that makes use of the lunar theory that is the astronomical standard.

The astronomical apogee is usually called 'Lilith' or 'True Lilith', but ILA uses the names 'Mean Black Moon' and 'Corrected Black Moon'.

Black Sun

The Black Sun is the aphelion, the point in the orbit of the Earth around the Sun that represents the empty focus in the ellipse. The position of the Black Sun changes very slowly.

Persephone and Vulcanus

Jean Carteret introduced the hypothetical planets 'Persephone' and 'Vulkanus', which would have an orbit beyond Pluto. An ephemeris exists for these points, but the positions are astronomically impossible, because they take into account neither Kepler's laws nor retrogradation. The effect of retrogradation ought to be large because of the distant positions of these hypothetical points. These hypothetical points can be regarded as symbolic points without material existence.

The ephemerides cover about a century, but Enigma extrapolates the positions for other periods. Because the motion is 100% uniform, this is sufficiently reliable.

Additional points

ILA uses several other points that have a position relative to one of the existing positions. In the table you can see all the points, a description and a brief meaning.

FACTOR	DEFINITION	BRIEF MEANING
Persephone	Hypothetical point	Relates to Pluto as Venus relates to Mars. Partner of Venus.
Vulkanus	Hypothetical point	Partner of Mercury. (Co-)ordination.
Black Moon	Mean apogee in the orbit of the Moon	Uniqueness, introversion, absorbs but does not reflect (as the Moon does). Cosmic treasure.
Corrected Black Moon	The apogee of the Moon with corrections for perturbations	Like the Black Moon.
Priapus	Mean perigee of the Moon (opposite to the Black Moon)	Adaptation, survival
Corrected Priapus	The perigee of the Moon with corrections for perturbations (opposite to the Corrected Black Moon)	Like Priapus.
Black Sun	Aphelion in the orbit of the Earth around the Sun	Meaning opposite to that of the Sun. Anti-authority, chaos, deconditioning.
Diamond	Perihelion of the Sun (opposite to the Black Sun)	Strongly resembling the Sun, but more explicit. Counterpart of the Black Sun.
Dragon	The point that forms a square with the North Lunar Node, in the direction of the signs	The hard armour of the ultimate form of consciousness. Perfectionism.
Beast	The point that forms a square with the North Lunar Node, in the direction opposite to the direction of the signs	Opposite to the Dragon: pure energy. Inspiration, where everything is possible.
