

Transits

Enigma Factsheet · Transits

Transits are the most elementary form of progressive astrology. You only need to calculate the positions of celestial bodies at the moment of an event.

Positions

The most important positions are longitude and declination. Horizontal positions — azimuth and altitude — change continuously throughout the day and are best avoided.

Enigma does not apply a parallax correction for transits, even if you have selected 'Topocentric' in the configuration. The value for parallax correction changes throughout the day, and for many events you only know the date. Moreover, the effects — from a progressive perspective — are only relevant for the Moon, which you will usually ignore for transits.
